oxides and their atomic arrangement. The author is of the opinion that there exists such a relationship which is to be detected by crystallographers. Also, the "molecules" U_nO_{2n+2} should be sought in order to obtain a clear conception of the chemical character of homology in this case. Finally, the author notes that the definition of this homology offers a new way of explaining the chemical nature of berthollides which are similar to the oxides having a varying composition $UO_{2.0-2.25}$.

Taking account of the homologous rule, these berthollides cannot be understood any longer as "phases of varying composition" or as a "continuous set of compounds". The new data call for a revision of opinions and indicate that the ranges of the above-mentioned compositions should be regarded as a continuous, discrete set of independent chemical substances. They have a common homologous rule and very similar chemical compositions, crystal structures, and properties. There are 1 figure and 23 references: 5 Soviet-bloc and 18 non-Soviet-bloc. The three references to English-language publications see in the body of the abstract.

Card 5/7

The homologous series of uranium...

(B. Belbboch, C. Piekarski, P. Perio, Ref. 23, Bull. Soc. franc. mineral. et cristallogr., 83, No. 7/9, 206 (1960)), cubic syngony has been confirmed by X-ray studies. A fourfold size of the constant lattice has been found: $a = 4 \cdot 5.433 = 21.73 \text{ \AA}$. This is indicative of the discrete chemical composition of U_4O_9 . In the cases of $n=3$, $n=4$, $n=5$, $n=6$,

and $n=8$, the atomic arrangement has not been defined exactly. It is noted that the increase of n in the above homologous series leads rapidly to very slight differences of the chemical composition between neighboring oxides. Here, the researcher finds innumerable discrete uranium oxides which, with respect to their composition, tend toward UO_2 , but never reach

it. In this way, the author explains the fact that there never exists an oxide having an ideal composition UO_2 , but always somewhat stronger

oxidized samples, whose x value is a little higher than 2: $UO_{2.008}$,

$UO_{2.010}$. Nevertheless, he supposes that also U_9O_{20} , $U_{10}O_{22} = U_5O_{11}$, $U_{11}O_{24}$ and others will soon be experimentally detected. Due to the insufficient knowledge of the crystal structure, it is still impossible to establish a relationship between the homology of the chemical composition of uranium

properties of U_3O_8 according to B. Chodura, Ya. Malý (Ref. 14: Kresheniyu struktury U_3O_8 . II Mezhdunarodn. konfer. OON po primeneniyu atomn. energii v mirnykh tselyakh, A/Conf. 15/P/2099, Czechoslovakia, 20, June 1958, 1958) and S. Siegel (Ref. 15: Acta Crystallogr., 8 No. 10, 617 (1955)). Both modifications of U_3O_8 oxides possibly have a varying composition with oxygen deficiency. $n = 4$. $U_4O_{10} = U_2O_5$. Since the equilibrium diagram of the U-O system has hitherto not been determined, the exact temperature and concentration limits of stability of U_2O_5 (as in the case of other uranium oxides) are still unknown. $n = 5$. In the neighborhood of $UO_{2.40}$, U_5O_{12} is tetragonal, which corresponds to the formula U_5O_{12} . $n = 6$. $U_6O_{14} = U_3O_7$ is tetragonal. $n = 7$. U_7O_{16} . Its theoretical composition $UO_{2.285} = U_7O_{16}$ really corresponds to the supposed experimental range $UO_{2.28-2.31}$ (P. Perio, Ref. 18: Bull. Soc. chim. France, 1953, 256, 840), which could not be exactly defined by P. Perio. $n = 8$. $U_8O_{18} = U_4O_9$. In the synthesis of a U_4O_9 monocrystal

however, are proved to exist as real oxides. They are denoted by corresponding formulas above the ordinates of compositions. In his discussion of known and hypothetical uranium oxides, the author avails himself chiefly of non-Soviet publications. $n = 1$. UO_4^{2-} , which has never been isolated in the free state, exists as an uranate ion UO_4^{2-} and as hydrates, e. g., $\text{UO}_4 \cdot 2\text{H}_2\text{O}$. $n = 2$. $\text{U}_2\text{O}_6 = \text{UO}_3$. Of these at least 5 polymorphous modifications are known. Recently, the author has confirmed data by W. H. Zachariasen (Ref. 12: Acta Crystallogr., 1, No. 5, 265 (1948)) on the hexagonal structure of the $\alpha\text{-UO}_3$ oxide. L. M. Kuznetsov of the author's laboratory produced this oxide by thermal decomposition of $\text{U}(\text{C}_2\text{H}_4)_2 \cdot 3\text{H}_2\text{O}$. Furthermore, the author has confirmed the cubic structure of the ReO_3 type for $\delta\text{-UO}_3$ by neutron diffraction measurements (discovered by E. Wait, Ref. 13, J. Inorg. and Nucl. Chem., 1, No. 4/5, 309 (1955)). The structure of two additional synthesized UO_3 oxides has hitherto not been determined by the author. $n = 3$. Ye. S. Makarov mentions the

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 139, no. 3, 1961, 612-615

TEXT: The author notes that the chemistry of the U--O system is very complicated due to the existence of oxides of varying composition as well as of the so-called "non-stoichiometric" oxides (not corresponding to a simple stoichiometric ratio between U and O). Since uranium exhibits a different chemical nature, and, according to its valence, can be similar to lanthanides or the elements IV A, V A, or VI A, the author assumes the existence of a general homologous rule (similar to W, Mo, V, and Ti) governing the composition of individual uranium oxides. According to his opinion, this is confirmed by data available in publications. In Fig. 1, the compositions of uranium oxides having the total formula U_nO_{2n+2} (where n denotes integers) are indicated on the axis of the compositions UO_x by vertical lines. The eight initial homologs of this series,

SOV/75-14-4-14/30

that all lines of the samples with the composition $\text{TiO}_{0-0.5}$ correspond to the hexagonal, tightly packed structure of α -titanium. Beginning with the oxide $\text{TiO}_{0.5}$, a system of weak lines occurs in the radiographs which indicate a phase with variable composition on the basis of TiO . The boundary for the uniformity of solid solutions of oxygen in α -titanium lies therefore approximately at the composition $\text{TiO}_{0.48}$. A figure shows the dependence between the lattice constants c and the corresponding contents of oxygen in the lowest titanium oxides. The accuracy of the radiographic method used was ± 0.1 wt%. There are 1 figure, 1 table, and 5 references, 2 of which are Soviet.

approximately 8000 kg/cm^2 , and kept for 15 hours in a quartz tube at $1000 \pm 20^\circ$ in order to obtain a uniform distribution of oxygen in the preparations. The annealed samples ($\text{TiO}_{0.05}$ and $\text{TiO}_{0.3}$) showed a reduction in weight of from $4 \cdot 10^{-4}$ - $7 \cdot 10^{-4} \text{ g}$, which was probably caused by sublimation. The obtained preparations were light-grey at the points of rupture, and became dark on being ground fine. The composition of the preparations was determined by the method of the vacuum melt (Ref 3). The radiographic determination of the lattice constant was carried out by the method of Debye-Scherrer. In order to obtain most accurate values for the lattice constants, the asymmetric method according to Straumanis and Jevins (Ref 4) was used. One of the most important conditions for the maximum accuracy of this method is the use of powdered samples (thickness $< 0.2 \text{ mm}$). The dimensions and conditions for the taking of X-ray spectra are indicated in the paper. The composition of the preparations under discussion, and the values of the corresponding lattice constants are shown in a table. The evaluation of the radiographs showed

TITLE:

Quantitative Determination of Oxygen in the Lowest Titanium Oxides by Radiographic Analysis

PERIODICAL:

Zhurnal analiticheskoy khimii, 1959, Vol 14, Nr 4, pp 463 - 465 (USSR)

ABSTRACT:

As the lowest titanium oxides the authors understand the solid solutions of oxygen in α -titanium with the composition $\text{TiO}_{0.42}$. Radiographic analyses of these compounds (Refs 1,2) show a steep course of the curves for the dependence of the lattice constant c on the oxygen content in α -titanium which crystallizes hexagonally. Based on this result, the radiographic method can be used for the quantitative determination of oxygen dissolved in α -titanium. In the paper under review, an experiment is made in this direction. The authors synthesized the lowest titanium oxides by saturating finely pulverized titanium with the calculated amount of gaseous oxygen at 500-550°. The powdery oxide preparations obtained were formed into small cylindrical columns at a pressure of

The Crystal Structure of the Compounds of Uranium with Germanium

Laue and oscillation photographs of single crystals of U_3Ge_4 showed the material to be orthorhombic with

$a = 5.86$, $b = 9.86$, $c = 8.96$ kX. UGe_2 was similarly

shown to be orthorhombic with $a = 4.11$, $b = 15.1$

$c = 3.97$ kX. $Z = 12$ and the dimensions of the unit

cell are similar to those of $ZrSi_2$ and $ZrGe_2$.

Comparisons of observed S.F.s and those calculated using $ZrSi_2$ coordinates gave a reliability factor of 0.25.

The $ZrSi_2$ structure with space group $D_{2h}^{17} = Cmcm$ is

therefore likely. It was confirmed that UGe_3 has the

$AuCu_3$ structure with $a = 4.197$ kX. There are 3 figures,

2 tables and 2 references, 1 of which is Soviet and

TITLE: The Crystal Structure of the Compounds of Uranium with Germanium (Kristallicheskaya struktura soyedineniy urana s germaniyem)

PERIODICAL: Kristallografiya, 1959, Vol 4, Nr 2, pp 183-185 (USSR)

ABSTRACT: Laue, oscillation and powder photographs showed that U_5Ge_3 is hexagonal with $a = 8.56$ and $c = 5.78$ kX. $d_{obs} = 13.4$ g/cm³ gives 16.8 atoms per cell representing $Z = 2$. By analogy the compound was assumed to have a structure of the Mn_5Si_3 (Mn_5Ge_3) type. An electron density projection onto 0001 was calculated. This showed that the structure is actually of the Mn_5Si_3 type. The space group is $D_{6h}^3 = C6/mcm$ with $4U_I$ in 4(d) positions; $6U_{II}$ in 6(g) positions with $x_U = 0.24$ and $6Ge$ in 6(g) positions with $x_{Ge} = 0.62$. Good agreement between observed and calculated structure factors is obtained.

On the Duality of the Chemical Nature of Actinides

70-3-5-4/39

actinides, lanthanides and the elements of the group IVa, Va, VIa is continued. An isostructural analogy is also to be found in the intermetallic compounds. The actinide elements with the elements of the IVa, Va, VIa groups enter continuous solid solutions with cubic centred lattice. A similar isomorphism does not exist in the systems of the actinides and lanthanides. The numerous isomorphisms between the compounds of the actinides and the IVa, Va and VIa groups on one hand and the similarity of the actinides to the lanthanides indicate that the actinides can not be denominated as transuranian elements, as their chemical nature shows duality. There are 1 figure, 7 tables, and 14 references, none of which are Soviet.

TITLE: On the Duality of the Chemical Nature of Actinides (O dvoystvennosti khimicheskoy prirody aktinidov)

PERIODICAL: Zhurnal Neorganicheskoy Khimii, 1958, Vol. 3, Nr 5, pp 1079-1088 (USSR)

ABSTRACT: This paper deals with the extensive experimental material on the crystallo-chemical analogy between the compounds of the actinides on the one hand and the compounds of the elements of the Va, VIa, IVa groups and the rare earths on the other. It was determined that a profound crystallo-chemical similarity exists between these groups. The oxides of ThO₂, UO₂, CrO₂, and CeO₂ not only have similar chemical properties, but also the structure of these compounds is similar to that of the oxides of the actinides. Furthermore the oxides have chemical properties similar to those of the oxides of the elements of the IVa, Va, VIa groups. In the groups of the nitrides, carbides, and borides, the isostructural analogy between the compounds of the

New Data on the Structure of BiIn_2 and the Possible Structure of $\text{TlBi}_{1.27 \rightarrow 1.59}$, NaHg_2 , UHg_2 , UZr_2 and TiU_2

compounds of type Ni_2In consists of the following: The lower limit of the axial ratio for the structural type Ni_2In is $c/a = \sqrt{3}/\sqrt{2} = 1.225$ (Ref 10). In fact, among all the experimentally established members of the structural type Ni_2In , among which one component should be a metal belonging to transition groups "A" and the second an element of subgroups "B", there are none which have an axial ratio < 1.225 . On the other hand, in the case of BiIn_2 , this ratio is equal to 1.197 which is less than 1.225. In addition, the compound BiIn_2 does not include a transition metal and consists of two elements of sub-groups "B". Low values for the axial ratios for: TiU_2 (0.59), UZr_2 (0.61) (Ref 11), UHg_2 (0.64) and NaHg_2 (0.64) suggest that probably these compounds have a structure of

Card 3/4

not take into account some very weak lines which were at first ascribed to some unknown impurity. However, the presence of such impurities was not established and doubts were felt about the correctness of the BiIn_2 structure given

in an early paper (Ref 1). In order to put this structure on a firmer basis, it was decided to study a monocrystal of this compound and the results of this work are now reported. X-ray studies of this BiIn_2 monocrystal have shown that this compound has a structure of type Ni_2In with an axial ratio $c/a = 1.197$. It is suggested that:

$\text{TlBi}_{1.27 \rightarrow 1.59}$, NaHg_2 , UHg_2 , UZr_2 and TiU_2 have an analogous structure. Monocrystal studies have shown that BiIn_2 has the following lattice constants:

$a = 5.496 \pm 0.001 \text{ \AA}$; $c = 6.579 \pm 0.001 \text{ \AA}$; $c/a = 1.197$.

The main crystallographic difference between BiIn_2 and

ABSTRACT: Among intermetallic compounds which have a hexagonal structure of the type AlB_2 there are a few cases with anomalously low ratio of axes c/a which is equal to about 0.6. On the other hand, in "normal" borides and halides of this type this ratio is roughly 1.0. Such "anomalous" intermetallic compounds are:

BiIn_2 (Ref 1), $\text{TlBi}_{1.27 \rightarrow 1.59}$ (Refs 2, 3), TiU_2 (Ref 4)
 UHg_2 (Ref 5), NaHg_2 (Ref 6) and UZr_2 .

The crystal structure determination of all these compounds was carried out by the powder method. In earlier studies of the crystal structure of BiIn_2 (Ref 7), the author did

Card1/4

data (up to 1957) on the crystal chemistry of simple compounds of actinide elements. The dual nature of actinides is discussed in order to show the similarity and difference of their chemical behavior with respect to other elements and to clarify their position in the periodic table. There are 117 references of which 13 are Soviet, 90 English, 9 German, 2 French, and 3 Italian.

*Structure of Alloys of Nickel with Aluminum in the β -Phase Region at High Temperatures. L. N. Guseva and E. S. Makarov (*Doklady Akad. Nauk S.S.S.R.*, 1961, 77, (4), 615-616). [In Russian]. Alloys contg. 60-66 at.-% Ni quenched from 1340° C. are single-phase and have a tetragonal structure. X-ray analysis of these alloys in the annealed state shows the presence of two phases, $\beta + \alpha'$ (Ni_3Al), in agreement with the equilibrium diagram of Bradley and Taylor (*Proc. Roy. Soc.*, 1937, [A], 159, 59; *M.A.*, 4, 241). The quenched alloys have a partially ordered body-centred structure. For the alloy with 60.6 at.-% Ni (Ni_3Al), $a = 2.663$, $c = 3.237$ kX, $c/a = 1.125$; $d = 6.66$; number of atoms in unit cell = 1.96. For the alloy with 66.6 at.-% Ni (Ni_3Al), number of atoms in unit cell = 2.01. The observed intensities of the reflections in an X-ray photograph of an alloy contg. 60.6 at.-% Ni, quenched from 1340° C., agree satisfactorily with the values calculated for Ni_3Al .

New data on the crystal structure of the β -phase of the system sodium lead. B. S. Makarov and Z. V. Popova. *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* 1951, 377-37. --An expl. study was made to det. the compn. range of the β -phase and the corresponding crystal structures. To prevent excessive reaction of the alloys with O_2 or moisture, data were obtained within 5 hrs. after prepn. of the alloys. The Pb was melted in an Fe crucible under a const. flow of Ar gas by use of an elec. furnace. Freshly cut Na was added when the temp. of the Pb was slightly above the liquidus and was stirred in. No flashing occurred. After a min. a sample for chem. analysis was pumped into a 1.5-mm. diam. glass tube, and a sample for x-ray analysis was pumped into a 0.4 to 0.8 mm. capillary of Lj deman glass. Both ends of the capillary were sealed to reduce the empty space. Homogenization was not needed. Debye x-ray patterns were obtained with a 57.3-mm.-diam. camera, Cu radiation, 35 kv., and 10 ma. Lattice consts. were accurate to ± 0.002 kX. Powder specimens gave poorer results than did the cast specimens. Chem. analysis was done by amalgamating the Pb, dissolving the Na in H_2O , and titrating the latter with 0.1 N HCl, with methyl orange. Duplicates agreed to 0.1%. Density measurements with a precision of $\pm 1\%$ were made with a pycnometer and Na-dried aviation gasoline. At room temp. the β -phase existed from 26.5 to 35.1 at. % Na. The lattice const. decreased with increasing Na content from 4.870 to 4.801 kX, and the d. decreased from 8.79 to 7.49, with an especially rapid fall near 35% Na. The no. of atoms per unit cell in the ordered Cu₃Au-type structure was calcd. as 3.95 up to about 33% Na, but at 35% Na it was only 3.65. No significant change

in the degree of order with increasing Na content was detected by measuring the relative values of a "structure" and of a "superstructure" x-ray line. A calcn. showed that the ratio of these values would change only by 2% in going from 27.0 to 33.0% Na.

Nomenclature and symbols for solid phases of variable composition. E. S. Makarov. *Doklady Akad. Nauk S.S.S.R.* 74, 1003-6 (1950).—Compds. of fixed and simple stoichiometric compn. will be represented conventionally: AB , AB_2 , A_2B_3 , etc. Compds. of fixed but nonstoichiometric compn. will be represented by AB_s , in which $s = n/a$ ($100-n$); $n = \text{at. \% of B}$. E.g., for the system Cu-Be contg. 70.0 at. % Be the formula is $\text{CuBe}_{0.7}$. Solid solns., the content of one of whose components may vary from 0 to a definite limit at a given temp. and atm. pressure, will be represented by $\rho\text{-AB}_{s_1 \rightarrow s_2} (t^\circ \text{C.})$, in which s is defined as above. Those solns. that exist in the form of several modifications will be distinguished by Greek letters: e.g., $\rho\text{-}\gamma\text{-FeCo}_{0.4 \rightarrow 0.6} (1140^\circ)$. Solid solns. of unlimited variability in compn. will be represented by $\rho_{\infty} - (A,B)$. Intermediate phases of variable compn. will be represented by $AB_{s_1 \rightarrow s_2} (t^\circ \text{C.})$; for berthollides and daltonides this type formula is preceded by b or d ; e.g., $b\text{-TiO}_{0.5 \rightarrow 1.5}$. The views of other workers are discussed. J. P. Danchy

Crystal structure of the γ -phase in the aluminum-magnesium system and the γ -phase in the thallium-bismuth system. E. S. Makarov. *Doklady Akad. Nauk S.S.S.R.* 74, 935-8 (1950).—An exptl. study at 20° of these intermediate solid solns. confirmed previous data on crystal structure. The γ -phase in Al-Mg has the α -Mn structure with a lattice const. that varies linearly with at. % Al between the soly. limits, $a = 10.5700 \pm 0.0003$ Å at 38.5 at. % Al and $a = 10.4480$ at 48.4 at. % Al. The γ -phase in Tl-Bi appeared to be essentially a disordered structure of the AlB₂ type; it had a hexagonal structure and had soly. limits of 56.0 and 61.4 at. % Bi. At 56, 58, and 60 at. % Bi the a and c values were 5.642, 5.644, 5.652 and 3.372, 3.375, 3.371. Density measurements showed that in both cases the phases are substitutional. The alloys were carefully prepd. to prevent loss by evapn. and the analyses were assumed to be those of the syntheses. Homogenization for 3 days at 450° and 7 days at 140°, resp., was followed by slow cooling.

Filtered Cu γ -radiation was used in a camera (11.7 mm in diam.)

Continuous transition between the tetragonal and the cubic forms of alloys of indium and thallium. E. S. Makarov (N. S. Kurnakov Inst. Gen. and Inorg. Chem., Acad. Sci. U.S.S.R., Moscow). *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* 1950, 485-91. —X-ray diffraction detns. on In-Tl alloys with up to 30.0 at. % Tl show that a tetragonal and a cubic form exist in the one-phase range of the alloys at room temp., not sepd. by a two-phase region. The tetragonal form lies in the range from 0 to 25.0 at. % Tl; the cubic form, from 25.0 up to Tl-rich limit of the compn. investigated. There is a continuous crystallographic transition between the 2 forms, with the lattice const. a increasing regularly with the Tl content, and the const. c and the ratio c/a decreasing up to the compn. 22.5 at. % Tl. The lattice constns. vary sharply but still continuously between 22.5 and 25.0 at. % Tl; with further increasing Tl content, from 25.0 to 28.0 at. %, the lattice constns. again vary smoothly. The curves of a and c merge at 25.0 at. % Tl, and the ratio c/a becomes = 1, i.e. the tetragonal form has gone over into the cubic form. In both the tetragonal and the cubic range the alloys are substitutional, with an unchanged no. of atoms in the elementary cell = 4, and the coordinates 0, 0, 0; $1/2, 0, 1/2$; $1/2, 1/2, 0$; 0, $1/2, 1/2$, corresponding to the original face-centered structure of In, with random distribution of the In and Tl atoms in the lattice. Homologous Groups of Phases [Nickel-Arsenide Phases]. E. S. Makarov (Izvst. Akad. Nauk S.S.S.R., 1946, [Khim.], (6), 569-580). (In Russian). The crystal structure and chemical character of phases of constant or variable composition can be brought under one general law, if these phases are considered within the framework of Mendeleev's periodic system. This law, called "homologous groups of phases", is observed in phases having, to some degree, heteropolar linkage. Within the limits of a given homologous group of phases, the chemical character of the linkage varies regularly with change in composition, and in some cases it is possible to trace the gradual transition of phases from the salt type to the intermetallic compound type. A group of nickel-arsenide phases (NiTe_2 , NiSb , NiTe , Ni_2In) illustrates the continuous transition from the salt type of phase, having a flaky structure of the CuI type, to intermetallic compounds of the Ni_3In type. Homologous groups explain the existence of nickel-arsenide phases displaced from the 1:1 composition characteristic of the ideal nickel-arsenide structure. The reason for the formation of "displaced" phases lies in the valency ratios of the elements composing the phases. Within the limits of the homologous group of phases of the nickel-arsenide type, the valency of the transition metal changes continuously and these phases must be regarded as chemical compounds of variable composition. — N. A.

Crystal chemistry of phases with the structures of NiAs type. I
 Relations between the structure types of NiAs, CdI₂, and Ni₂In. F. S.
 Makatov, (Bull. Acad. Sci. USSR, Div. Chem., 1944, 114)
 1211. The three structures are separate stages in the filling up of
 the same crystal lattice, with the less noble partner hexagonally
 close-packed. The CdI₂ type appears when half of the octahedral
 holes are filled and is the most open structure, the NiAs type is
 intermediate, and the Ni₂In type appears when all the holes are filled.
 The solid solutions formed in the alloys of Ni with Fe, Sb, Sn, and
 In within the range 33.3 - 66.6 at. % of Ni connect all three types of
 structure through a continuous series.

Form of the first Brillouin zone in the case of hexagonal structure of nickel arsenide type. E. S. Makarov (*Compt. rend. Acad. Sci. U.R.S.S.*, 1943, 40, 191-193). The low or negative temp. coeff. of electrical conductivity in Fe-Ni-Sb alloys with Ni arsenide structure implies nearly complete filling up of the Brillouin zone, which should include ~ 2.5 electronic states per atom. Data from powder photographs show that the shape of the Brillouin zone is a combination of 3 types of plane, (002-112), (200-130), and (002), with vol. in the K -space $(32a^3 - 2\pi/3\sqrt{3}a^3c)$ and $(16a^3 - c^3)/6a^3$ states per atom. Vals. for Fe-Sb (47.1 at.-% Sb), Co-Sb (48.2 at.-% Sb), and Ni-Sb (49.46 at.-% Sb) are 2.402, 2.372, and 2.386 states per atom. Overlapping into the second zone occurs across the (002) plane, and accounts for electrical properties and metallic character. L. J. J.

<p><i>m</i></p> <p>*Continuous Transition Between the Daltonide and the Berthollide Phases in the System Iron-Nickel-Antimony. N. V. Ageev and E. S. Makarov. (Compt. rend. (Doklady) Acad. Sci. U.R.S.S., 1943, 38, (1), 20-21). [In English.] In the nickel-antimony system a phase with the nickel arsenide type of structure exists between 46.4 and 54.4 at.-% antimony. Property-composition curves give sharp peaks at the composition Ni8b, showing the phase to be a "daltonide." Alloys containing an excess of nickel over that required for Ni8b are built up according to an interstitial plan, while those with a deficit of nickel belong to the class of structures with defect lattices. In the iron-antimony system the corresponding phase with the nickel arsenide structure is stable from 42 to 48 at.-% antimony. This range does not include the composition Fe8b and the phase is a "berthollide"; it has an excess of iron and is of the interstitial type of structure. In the system iron-nickel-antimony a continuous series of solid solutions exists between these two phases. These ternary alloys have the nickel arsenide structure, while those that have more iron and nickel or more antimony than corresponds with the line Ni8b-Fe8b have interstitial or defect structures, respectively.</p> <p style="text-align: right;">—G. SOLID SOLUTIONS WITH A DEFECTIVE LATTICE IN THE NICKEL ANTIMONY SYSTEM.
 E.S. MAKAROV (IZV-S . SEKT. FIZIKO KHIM. ANAL., 1943, 16, (1), 149-157)
 (In Russian) The phase in the nickel-antimony system is homogeneous in the
 range 46.4 to 54.4 at.-% antimony, as is shown by examination of the
 microstructure and by precision lattice-parameter measurements. The basis
 of the γ - phase is the chemical compound Ni Sb, the evidence for which is
 found in the breaks in the curves of electrical resistance and its temp.
 coeff. Comparison of the dimensions of the unit cell with the density and
 intensity of the lines on Debye X-ray photographs leads to the conclusion that
 γ -phase alloys rich in nickel belong to the interstitial type, while anti-
 mony-rich γ -phase alloys belong to the defective-lattice type of solid
 solution. It is shown that the change in the number of atoms in the unit
 cell that occurs in the γ -phase is connected with the necessity
 for the number of electrons in the unit cell being maintained const. NA

"Physico-Chemical Study of the Phases Having a Nickel Arsenide Structure in the Systems Iron-Antimony, Cobalt-Antimony, and Nickel-Antimony. N. V. Ageev and E. S. Makaryy (*Izvest. Akad. Nauk S.S.S.R.*, 1943, [Khim.], (2), 87-91).—[In Russian.] (*Cf. Compt. rend. (Doklady) Acad. Sci. U.R.S.S.*, 1943, 28, 20; *Met. Abs.*, this vol., p. 110. The phases having a nickel arsenide structure in the nickel-antimony, cobalt-antimony, and iron-antimony systems have been studied by means of X-ray and microstructural examination and by determinations of electrical resistance and density. (1) The γ phase of the nickel-antimony system is found to exist over the range 46.4-54.4 at.% antimony; it includes the compound NiSb and the phase is therefore a daltonide. Comparison of the density of the alloys as measured directly and as derived from lattice spacings shows that γ -phase alloys on the nickel-rich side of NiSb have structures of the interstitial type, while those on the antimony-rich side have structures of the defect type. (2) The γ phase of the cobalt-antimony system lies in the range 43.4-49.2 at.% antimony; this range does not embrace the compound CoSb and the phase is therefore a berthollide. It has a structure of the interstitial type. (3) The ϵ phase of the iron-antimony system exists over the range 42-48 at.% antimony and is likewise a berthollide, being formed by the intrusion of iron atoms interstitially into the lattice of the hypothetical compound FeSb. The hardness, heat of formation, melting point, and interatomic distances of the three phases are compared, and the view is advanced that the strength of chemical linkage decreases in the order: NiSb > CoSb > FeSb.—N. B. V.

A.P.S. *Chemical & Metallurgical*

Röntgenographic determination of structure of ternary solid solutions of magnesium, silicon, and aluminum.
V. G. KUZNETSOV AND E. S. MAKAROV. *Izvest. Sektora*

Fiz. Khim. Anal. Inst. Obshch. & Neorg. Khim., 13, 177-80 (1940); *Khim. Referat. Zhur.*, 4 [9] 35-36 (1941).
—Using the precision method of Preston, the authors determined the parameters of the lattice of the ternary solid solution Al-Mg-Si for 6 radial cuts starting at Al and going toward the side Mg-Si up to 2.2 wt. % (Mg + Si) as well as for Al-Si alloys up to 2.2 wt. % Si. Isotherms were constructed for the solubility of Mg and Si in Al at 550°, 500°, 400°, and 200°. The solubility of Mg and Si in Al at 200° is not more than 0.1% of the sum (Mg + Si) of the region delineated by the system Al-Si-Mg₂Si. The difference in the nature of experimental and calculated curves for the parameters of the lattice, assuming an atomic structure of a solid solution for alloys annealed from 500°, leads to the belief that the solid solution Al-Mg₂Si is molecular in its structure. On Debye diagrams of alloys annealed after heating at 550° and 200°, only lines corresponding to the lattice of Al were observed. Annealed and slowly cooled alloys containing 2.2% of Mg + Si and located on the pseudobinary and adjacent sections show, on Debye diagrams, weak additional lines corresponding to the lattice Mg₂Si.
M. Ho

COMMON ELEMENT		PRECISE AND PROPERTIES INDEX	
<p>*X-Ray Investigation of the Ageing of Aluminium Magnesium Silicon Alloys. V. G. Kuznetsov and E. S. Makarov. (<i>Izv. Akad. Nauk. Fiziko-Khimich. Analiz. (Ann. Secteur Anal. Phys.-Chim.)</i>, 1940, 13, 191-200). [In Russian.]</p> <p>Aluminium-magnesium-silicon alloys with compositions along the two sections having constant aluminium contents of 98.2 and 98%, were investigated. The alloys were quenched after solution heat treatment at 550° and 600° C. Some were subsequently work hardened by powdering by filing. The alloys were allowed to age at room temperature and were also subjected to artificial ageing at 150°, 175°, and 200° C. for various periods of time. Lattice parameters were measured using both the Preston and the Sachs X-ray cameras. Lattice parameter changes on room-temperature ageing were within limits of experimental error. At the elevated temperatures the solid solution decomposed with a change in the lattice parameter which tended to approach that of pure aluminium. Alloys containing magnesium in excess of Mg₂Si showed no change in lattice parameter and it is concluded that the solid solution does not undergo decomposition. At 150° C. in alloys with 1-2% magnesium, silicon decomposition was associated with considerable lattice distortion, distortion being most marked during the earlier stages of ageing. Distortion increased with an increase in magnesium content. In alloys with Mg:Si 1:1 and more, distortion appeared after 5 minutes and had not disappeared after ageing for 40 hrs. Decomposition is irregularly distributed and this results in a series of lines instead of the doublet (333) K₂ and K₄ in the X-ray photographs. Deformation after quenching considerably accelerates the decomposition process.---A. R.</p>

<p><i>*The Structure of the β and ϵ Phases in the Copper-Antimony System.</i> N. W. Ageev and E. S. Makarov (<i>Izvest. Sekt. Fiziko-Khimich. Analiza. (Ann. Secher Anal. Phys.-Chim.)</i>, 1940, 13, 171-176).--[In Russian.] Alloys with 60-70 wt.-% copper, investigated by microscopic examination and the Debye X-ray method, confirmed in general the equilibrium diagram of Murakami and Shibata (<i>Met. Abs.</i>, 1937, 4, 38). The ϵ phase is homogeneous between 67.89 and 68.08% copper, which is more on the antimony side than is given by M. and S. The eutectoid point is situated at about 62.4% copper. Alloys with 60.00 to 64.04% copper consisted of the homogeneous β phase, the limit on the copper side being at 65% copper. The ϵ phase, in agreement with Morris-Jones and Evans (<i>Met. Abs. (J. Inst. Metals)</i>, 1928, 39, 638), was found to have a hexagonal close-packed lattice with $a = 2.723-2.745$, $c = 4.322-4.340$ A. The structure of quenched specimens of the β phase was found to be cubic with 16 atoms per unit cell and a parameter of 5.914 A. The β phase has an orderly arrangement of atoms resembling the $FeAl_3$ structure, and corresponds to the formula $Cu_{12}Sb_4$ (Cu_3Sb).--A. H.</p>

***An X-Ray Study of the Structure of Ternary Solid Solutions of Aluminium with Magnesium and Silicon, and Their Ageing.** V. G. Kuznetsov and E. S. Makarov (*Compt. rend. (Doklady) Acad. Sci. U.R.S.S.*, 1959, [N.S.], 23, (3), 235-240). — [In English.] K. and M. have made an X-ray study of magnesium-silicon-aluminium alloys situated on 6 lines radiating from the aluminium corner of the system and containing up to 2% total magnesium + silicon. The solid solubility limits at 600°, 500°, 400°, and 300° C. in the aluminium corner of the diagram have been established from the X-ray data. Discrepancies between the curves showing variation of parameter with composition, as calculated and as experimentally determined, lead, in conjunction with other observations, to the conclusion that in aged alloys Mg_2Si is present in molecular form in the aluminium-rich solid solution. All attempts to detect lines from the Mg_2Si lattice in X-ray photographs of alloys aged for 150 hrs. at 200° C. have, however, failed, a fact which is ascribed to the smallness of the amount of compound present.—N. B. V.

TITLE: An Unattended Fuel Oil Pump Room (Mazutonasosnaya bez obsluzhivayushchego personala)

PERIODICAL: Promyshlennaya Energetika, 1958, No.1,
pp. 16 - 17 (USSR)

ABSTRACT: This brief note describes the way in which the fuel-oil pump-room of the Chelyabinsk Forge and Press Works (Chelyabinskiy kuznechno-pressovoy zavod) was made automatic. When the pressure alters in the fuel-oil pressure line, there is a change in the pressure of transformer oil in a tank which operates a membrane-type pressure-regulator. For purposes of remote control of fuel-oil pressure and temperature, a contact manometer and light-signal is installed. The oil-pressure installation that delivers oil to the regulator operates at a pressure of 6 kg/cm² with an output of 14 litres/min. It is driven by a motor of 0.8 kW. The total cost of making the pump room automatic was about 1 600 roubles and it has been operating reliably unattended for more than a year. There is 1 figure.

TITLE: Nuclear gamma resonance in highly dispersed tin ✓

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 51, no. 1, 1966, 118-120

TOPIC TAGS: tin, nuclear resonance, aerosol, Mossbauer effect, Mossbauer spectrum, temperature dependence

ABSTRACT: The Mossbauer effect was investigated in highly dispersed tin particles having diameters of 250, 370, 600, and 1550 Å. The dispersed tin was produced by evaporating liquid drops in a helium or argon atmosphere and condensing the vapor into aerosol particles. The particle size was regulated by the rate of flow and also depended on the gas. The mean particle size was determined with an electron microscope. The spectrum for the highly dispersed tin consisted of a single line characteristic of ordinary polycrystalline β -Sn with a chemical shift of 2.6 mm/sec (relative to SnO_2). The probability of the Mossbauer effect f' was measured as a function of the temperature (T) and particle diameter (d) from the area under the spectral absorption curve. The results show that f' diminishes with decreasing particle diameter, starting with $d \approx 600$ Å. The temperature dependence is steeper. The variation with particle sizes is connected with the influence of the surface. The Debye temperature is determined

trodynamic 500-channel gamma resonance spectrometer. Cobalt-57 was used as the gamma source. All measurements were taken at liquid nitrogen temperature. The two starting solutions contained: 8 mg of Fe^{+3} ions 60% enriched with Fe^{57} isotope and 12 mg Fe^{+2} with natural content of Fe^{57} . After obtaining the Mossbauer spectra on the starting solutions they were mixed in a cuvette and frozen at 80°K. After mixing, the spectral parameters of the solution are characteristic for Fe^{+2} with higher line intensities than in the starting solution of Fe^{+2} (see fig. 1) indicating increase of the concentration of Fe^{57} in the Fe^{+2} form due to the electron exchange reaction

The Fe^{+3} line is weak due to the very small f' for Fe^{+3} ion and the high degree of electron exchange. Changes in the spectrum in the course of the 2 hr measurement period indicate that some electron exchange takes place in the frozen solutions at 80°K. The experiment shows the effectiveness of this method in the investigation of electron and isotope exchange. In the investigated system electron exchange between Fe^{+2} and Fe^{+3} proceeds rapidly, but at a measurable rate. It is planned in the future to use the method for the quantitative investigation of the

 SOURCE: AN SSSR. Doklady, v. 165, no. 6, 1965, 1347-1349
 TOPIC TAGS: iron compound, Mossbauer effect, charge exchange, *isotopes, Mossbauer spectrum, redox reaction*
 ABSTRACT: The method consists in successively enriching each of the reacting components in the given complex system with the Mossbauer isotope of the element which is in the given component (for example Fe⁵⁷, Sn¹¹⁹) and then studying the changes in the Mossbauer spectrum of the reaction products as compared with the spectrum of the natural isotope components. Variations can be extremely fruitful in the study of rapid redox processes or isotope exchange and also for the study of chemical processes at low temperatures. The experiments were conducted with Fe²⁺ and Fe³⁺ ions in Cl⁻ and SO₄²⁻-containing media at pH ~1. The Mossbauer spectra were measured on an elec-

that the former is attached to the surface by physical adsorption, and the latter is held by chemisorption. With increasing temperature, the doublet components on the spectrum (which consist of a singlet and a doublet) become asymmetrical, and the electric field gradient at the Sn^{119} nucleus increases over the value for crystalline SnO . Estimates are presented for the absolute values of the rms displacements of the molecule $\text{SnO}_2 \cdot n\text{H}_2\text{O}$ on the surface, and of the tin atoms within the molecules. The energy of the zero-point vibrations of the tin atoms and molecules, the energy at which the binding between the molecule and adsorption center on the surface vanishes, the absolute value of the rms displacement of the tin atom within the SnO molecule normally and parallel to the surface, and the temperature dependence of these quantities are also estimated. Authors thank I. Ye. Neymark, V. M. Chertov, and I. Ye. Garzancov for interest in the work and for help with the experiments, and Yu. M. Kagan for a discussion of the results. TITLE: Investigation of the dynamics of motion of tin atoms on a silica gel surface by means of the Mossbauer effect 27

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 5, 1965, 1424-1430

TOPIC TAGS: temperature dependence, electric field, ion exchange, calcium cryostat, temperature measurement, gamma spectrometer, chemisorption
 ABSTRACT: The authors studied the dynamics of motion of tin atoms adsorbed on a silica gel surface with specific area 300 m²/g and particle diameter ~100 A. A monomolecular layer of tin was produced on the surface by successive ion exchange of the hydrogen atoms contained in the hydroxyl on the surface, first with Ca²⁺, and then with Sn²⁺. A special cryostat was constructed for the temperature measurement which could maintain any temperature between 90 and 300K accurate to 0.1°. All measurements were made with the nuclear gamma-ray resonance spectrometer described by the authors earlier (Zavodskaya laboratoriya, no. 12, 1965). The experimental results indicate that the tin atoms exist on the surface in two states, tetravalent and divalent. The temperature dependence of the intensity of the Mossbauer effect shows

when the test samples are saturated or directly placed into the chrome-plating mixture rather than placing them into the powder mixture. Fortunately, the grains of ferric chromate protect the iron from losses which would result in the formation of halogenates. In addition to the above, the formation of chromium halogenates directly near the surface of iron results in a higher local concentration of chromium. Thus, in order to obtain a more intensive adsorption of chromium on the surface of iron, the test samples must be placed into the chrome-plating mixture with the addition of ammonium iodide to the mixture. Orig. art. has: 1 figure, and several formulas.

TITLE: Effect of halide selection on the chrome-plating of iron 18

SOURCE: Zhurnal prikladnoy khimii, v. 36, no. 4, 1963, 800-806

TOPIC TAGS: chrome-plating technique

ABSTRACT: The experimental study shows that by increasing the atomic number of the halide which is introduced into the chrome-plating mixture, the quantity of chromium adsorbed on the surface of iron increases during the chrome plating process while the exchange factor m is expressed as follows: $m = q_{\text{sub } 1} / A_{\text{sub } 1}$ where $q_{\text{sub } 1}$ and $q_{\text{sub } 2}$ is the weight of adsorbed chromium and lost iron respectively. $A_{\text{sub } 1}$ and $A_{\text{sub } 2}$ are their atomic weights. Thermodynamic calculation showed that the increase of quantity of chromium adsorbed when the change is made from fluoride to iodide is explained by the fact that, with an increase of the atomic number of a halide, a higher concentration of chromium halide in the gaseous form is observed. At the same time, the decrease of exchange factor m is explained by the decrease of chromium concentration or iron which are reduced by hydrogen. Best results are obtained

TITLE: The coating of iron and steel with aluminum by vacuum evaporation

PERIODICAL: Zhurnal prikladnoy khimii, v. 35, no. 8, 1962,
1748-1752

TEXT: The authors present the results of their study of this process, stating that their method possesses the following advantages over conventional aluminizing processes: 1) The percentage of Al in the diffusion layer is lower, 2) the coated surface remains plastic and the thickness of the deposit can be controlled precisely, 3) the surface is clean and even and the volume increase of coated tools is very small. The method requires however a complicated and expensive equipment. The depth of the diffusion layer varies between 200 and 230 μ ; the Al content is up to 7 %; the increase of temperature markedly increases the Al content; the distribution curve of Al in the layer has two branches corresponding to Al diffusion into α - and β - Fe. The lowering of vacuum from 3×10^{-5} to Card 1/2

TITLE: On the mechanism of metal siliciding

PERIODICAL: Akademiya nauk Ukrayins'koyi RSR. Dopovidi, no. 1,
1962, 50 - 53

TEXT: On the basis of thermodynamic experiments and calculations the authors discuss the siliciding of iron, copper and nickel in the vapor phase. The experimental process is carried out in a two-zone furnace, the gas phase consisting of a mixture of SiCl_4 with argon at partial pressure 0.263 at. In the first zone of the furnace at temperature t_1 it is assumed that the reaction I. SiCl_4 (gas) + Si (solid) = 2SiCl_2 (gas) takes place. For the second zone at temperature $t_2 \leq t_1$, the following reactions are proposed: II. 2SiCl_2 + x Me (solid) = Si (alloyed with Me) + SiCl_4 (gas); III. SiCl_4 (gas) + b Me (solid) = SiCl_2 (gas) + Me_2Cl_2 ; IV. SiCl_2 (gas) + x Me (solid) = Si (alloyed with Me) + Me_bSi_2 (gas); V. SiCl_4 (gas) + x Me (solid) = Si (alloyed with Me) + Me_bCl_2 (gas) [Abstract]

cementite does not absorb antimony and its presence in the steel reduces the active surfaces of the specimens. Corrosion tests on various steels showed that their resistance-to-corrosion in a 1% solution of HNO_3 increased by a factor of 3 and

corrosion of commercial iron in a 10% solution of NaCl decreased by a factor of about 2. In the initial state, the weight loss after 1 and 3 days, respectively, amounted to 0.27 and

0.59 mg/cm^2 for commercial iron in a 10% NaCl solution and the respective values for Sb-saturated specimens were 0.18

and 0.33 mg/cm^2 . No increase of the resistance-to-corrosion of steel saturated with Sb was observed in a 10% solution of HCl and H_2SO_4 . The following conclusions are arrived at:

iron and steel can be saturated with Sb or Sn by evaporation in vacuum. The diffused Sn represents a solid solution of substitution of Sn in Fe, whilst the Sb forms a solid solution corresponding approximately to the phase FeSb . In both cases, an increase in volume is observed which is slight in

Card 4/6

Diffusion Saturation of

26571
S/129/61/000/008/004/015
E073/E335

range of the γ -iron stops extending at a carbon content of about 0.8%. The results of corrosion tests (in a 1% solution of HCl, in a 0.5% solution of NaCl and a 1% solution of H_2SO_4) of specimens saturated with Sn at 1 050 °C for 4 hours show that the resistance-to-corrosion in a 1% solution of HCl or H_2SO_4 increases 3-5-fold but does not change greatly in a 0.5% solution of NaCl. An antimony layer, produced by diffusion, has a small depth, is hard and brittle (the microhardness being 380 compared with 70 kg/mm² of the base material) and there is a sharply defined boundary relative to the base metal. The quantity of absorbed antimony and the increase in volume are considerable; the calculated average antimony concentration in the layer is about 68%, corresponding to the compound FeSb. With increasing temperature of the process, the brittleness of the diffusion layer increases and the surface of the specimens becomes less smooth. The optimum saturation temperature is 500 - 600 °C. The antimony saturation did not change greatly when the vacuum was reduced to 1 mm Hg. With increasing carbon content the antimony saturation (at 550 °C for 3 hours) of the steel became less. It can be assumed that

Card 3/6

EC73/E335

Diffusion Saturation of

The diffusion layer has a columnar structure and there is a line of separation between the layer and the base material. The curve characterising the change in the tin concentration along the depth of the diffusion layer has two sections, one which corresponds to the distribution of tin diffusing into α -iron, whilst the other corresponds to the diffusion into γ -iron. If the vacuum is only 1 mm Hg, the quantity of tin absorbed at 1 050 °C during 6 hours decreases from 2.21 - 1.82 mg/cm² and the depth of the diffusion layer decreases from 100 to 80 μ . In the case of saturation of carbon steel it was found that the depth of the diffusion layer, the quantity of the absorbed tin and the increase in volume would be less with increasing carbon content up to 0.8% (Table 1). This is attributed to the fact that the range of γ -iron increases with increasing carbon content. Since the coefficient of diffusion of tin and γ -iron is lower than that of α -iron, the absorption of tin will be less intensive. Apparently the

TITLE: Diffusion Saturation of Iron and Steel with Tin
and Antimony

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
1961, No. 8, pp. 18 - 22

TEXT: Published data on the subject are contradictory. The authors investigated the possibility of saturating iron and steel with tin and antimony and the corrosion-resistance of such diffusion layers. Specimens of 10 mm diameter, 5 mm high were saturated in vacuum ($2 - 5 \times 10^{-2}$ mm Hg) by evaporation of tin and antimony powder. The investigations were carried out on commercial iron and on steel 20.45. γ_8 (U8) and γ_{12} (U12). The results of saturation of commercial iron indicate that the concentration of tin on the surface of the specimen increases slowly with increasing temperature of the process. However, the quantity of absorbed tin, the depth of the diffusion layer and the volume of the specimen increase rapidly with increasing temperature of the saturation process.

TITLE: The Effects of Graphite Distribution and Heat Treatment on the Mechanical Properties of Cast Iron Under an All-Round Uneven Pressure (Vliyanie razmerov grafita i termicheskoy obrabotki na mekhanicheskiye svoystva serogo chuguna v usloviyakh vsestoronnego neravnornogo szhatiya)

PERIODICAL: Dopovidi Akademii nauk Ukrain's'koi RSR, 1959, Nr 3, pp 286-289 (USSR)

ABSTRACT: Using the method of academician B.D. Grozin [Ref 17], the authors studied the effects of the dispersity of graphite and heat treatment on the mechanical properties of cast iron under conditions of soft loading, that imitated the practical contact application of loads. Experiments were made on 10, 15, 20 and 30 mm in diameter cast iron cylinders cast in the ground. They consisted of 3.35% C, 1.80% Si, 0.48% Mn, 0.120% P, 0.185% S, and had a hardness of 101, 100, 95 and 90 units. Microstructurally, cast
